33 Abstract

34 **Background:** In British Columbia (BC), Canada, “HIV Treatment as Prevention” (TasP),
35 encompassing widespread HIV testing and immediate initiation of free ART, was piloted in 2010
36 under the Seek and Treat for Optimal Prevention of HIV/AIDS initiative (STOP). We compared
37 the time from HIV diagnosis to antiretroviral therapy (ART) initiation, and from ART initiation to
38 first virologic suppression before and after the implementation of STOP.

39
40 **Methods:** This population-based cohort study used longitudinal data of all diagnosed people living
41 with HIV (PLWH) in BC. Eligible PLWH were ≥ 18 years old, ART naïve, and newly diagnosed
42 in BC during 2005-2016. Virologic suppression date was the first of ≥ 2 consecutive viral load
43 measures < 200 copies/mL within four months. Negative binomial regression models assessed the
44 effect of STOP on the time from diagnosis to ART initiation, and from ART initiation to
45 suppression, adjusting for confounders.

46
47 **Results:** PLWH diagnosed before (N=1601) and after STOP (N=1700) were significantly
48 different: 81% vs. 84% were men, 30% vs. 15% ever injected drugs, and 27% vs. 49% had ≥ 350
49 CD4 cells/ μL at diagnosis. STOP was associated with a 65% shorter time from diagnosis to
50 treatment (adjusted mean ratio: 0.35 [95%CI: 0.32-0.38]) and a 22% shorter time from treatment
51 to suppression (adjusted mean ratio: 0.78 [95%CI: 0.72-0.85]).

52
53 **Interpretation:** In a population with universal health coverage, a TasP-based intervention was
54 associated with accelerating progress towards the United Nations’ 90-90-90 target. Our results

59 Introduction

60 The personal and public health benefits of early initiation of antiretroviral treatment (ART) are
61 well documented (1–5). In addition to decreasing morbidity and mortality among people living
62 with HIV/AIDS (PLWH) (1–3), ART has also been shown to reduce HIV incident cases in a
63 population (4,5). The latter led to the conception of “HIV Treatment as Prevention” (TasP), the
64 scaling-up of testing followed by the immediate initiation of ART, as a strategy for reducing AIDS-
65 related morbidity and mortality and, simultaneously, the spread of HIV (6–8). The success of TasP
66 on HIV transmission relies on the ART-led suppression of HIV replication, resulting in sustained
67 undetectable viral load in bodily fluids and an effectively zero risk of sexual transmission of HIV
68 - referred to as “undetectable=untransmissible” (U=U) (9,10).

69 To achieve the “End of AIDS as Pandemic” goal by 2030, the United Nations Joint AIDS
70 Programs (UNAIDS) proposed the TasP based 90-90-90 Target constituting at least 90% PLWH
71 diagnosed, 90% diagnosed PLWH on ART and 90% ART-treated PLWH virologically suppressed
72 by 2020 (11). Meeting the 90-90-90 Target would yield in a dramatic decrease in AIDS-related
73 morbidity and mortality and HIV new infections within a decade (12,13). The global progress
74 towards the 90-90-90 Target has been encouraging despite political, fiscal and programmatic
75 challenges (14–18). In British Columbia (BC), Canada, TasP was piloted in 2010 and subsequently
76 expanded province-wide under the publicly-funded Seek and Treat for Optimal Prevention of
77 HIV/AIDS initiative (STOP HIV/AIDS; hereinafter referred to as STOP). STOP used TasP as a
78 framework to address the HIV care continuum including widespread HIV testing, immediate ART
79 initiation, public health follow-ups for care interruptions, and targeted community outreach (19).
80 By 2016, BC achieved 84-85-93 (20); by December 2020, BC surpassed the 90-90-90 Target (21).

1
2
3 81 Evidence-based strategies that improve HIV clinical outcomes in a timely manner are
4
5 82 needed to inform future prevention and care efforts. As such, this study aimed to assess the
6
7 83 population-level impact of a TasP-based intervention in accelerating the progression towards the
8
9 84 UNAIDS 90-90-90 Target by comparing: (1) the time from HIV diagnosis to ART initiation, and
10
11 85 (2) the time from ART initiation to virologic suppression, before and after the implementation of
12
13 86 STOP (2005-2009 and 2010-2016, respectively). To examine whether STOP affected various
14
15 87 population subgroups equally, analyses of both outcomes were further stratified by demographic
16
17 88 and clinical characteristics.

89 **Methods**

90 **Study setting**

91 The BC Centre for Excellence in HIV/AIDS Drug Treatment Program (DTP) has been responsible
92 for ART distribution in BC since 1992 (22). ART and routine laboratory monitoring (including
93 plasma viral load [pVL] and CD4 cell counts) are free-of-charge for all PLWH. BC's HIV
94 therapeutic guidelines advise ART eligibility (23), with the minimum CD4 count to initiate ART
95 evolving from 200 cells/ μ L before 2008 to 350 cells/ μ L in 2008 and 500 cells/ μ L in 2010. Since
96 2012, ART is prescribed regardless of CD4 count. The recommended first-line ART regimens
97 have also evolved. Credited with faster virologic suppression and reduced drug resistance (24,25),
98 integrase strand-transfer inhibitor-based (INSTI) ART has been available in BC as a first-line
99 therapy option since 2011 for raltegravir, 2013 for elvitegravir, and 2014 for dolutegravir.

100

101 **Study design**

102 In this population-based cohort study, eligible participants included ART-naïve PLWH aged \geq 18
103 years, who were diagnosed between January 1, 2005 and December 31, 2016, and initiated ART
104 for the first time through the DTP. Longitudinal individual-level data on PLWH in BC were
105 obtained from the STOP population-based cohort through linkages between the DTP clinical
106 registry (22), and various provincial administrative datasets containing health information (26–
107 31). The cohort has been described elsewhere (26).

108

109 **Outcomes and exposures**

110 Our outcomes were time from HIV diagnosis to ART initiation (time Dx-Tx) and from ART
111 initiation to first virologic suppression (time Tx-Vx). Our exposures were HIV diagnosis and ART

1
2
3 112 initiation eras, each grouped into pre-STOP (2005-2009) and post-STOP (2010-2016). Diagnosis
4
5 113 date was the first instance of a positive HIV antigen/antibody test, a detectable pVL, an HIV-
6
7 114 related hospitalization, three HIV-related physician visits, an AIDS-defining illness, or ART
8
9 115 dispensation (32). ART initiation date was obtained from the DTP. Virologic suppression date was
10
11 116 the first instance of ≥ 2 consecutive pVLs < 200 copies/mL within four months. PLWH with < 4
12
13 117 months of follow-up upon ART initiation, hence unable to meet the above virologic suppression
14
15 118 definition, and those who did not achieve suppression during the study period were excluded from
16
17 119 the time Tx-Vx analysis.
18
19
20
21

22 120

23 121 **Potential confounders**

24
25
26 122 The following potential confounders were investigated: gender (female, male), age (< 30 , 30–39,
27
28 123 40–49, ≥ 50 years), health authority (HA) of residence (Fraser, Interior, Northern, Vancouver
29
30 124 Coastal, Vancouver Island, unknown), CD4 count (< 200 , 200–349, ≥ 350 cells/mm³, unmeasured),
31
32 125 ethnicity (White, non-White, unknown), and HIV acquisition risk group (gay, bisexual, and other
33
34 126 men who have sex with men [gbMSM], people who have ever injected drugs [PWID],
35
36 127 heterosexual/other, unknown). Note that age, HA of residence and CD4 count were measured at
37
38 128 diagnosis and ART initiation for time Dx-Tx and Tx-Vx analyses, respectively. For Tx-Vx
39
40 129 analysis, additional treatment-related potential confounders, measured at ART initiation, were also
41
42 130 assessed: pVL (continuous in log₁₀ copies/mL) and first-ART class (non-nucleoside reverse
43
44 131 transcriptase inhibitor [NNRTI], protease inhibitor [PI], INSTI, INSTI combined with NNRTI
45
46 132 and/or PI, others).
47
48
49
50

51 133 Of note, Vancouver Coastal HA cares for $> 50\%$ of BC's PLWH, while Northern is one of
52
53 134 the most remote HAs. CD4 count was the closest measure within a year before diagnosis and ART
54
55
56
57
58
59
60

1
2
3 135 initiation dates, respectively. If unavailable, the closest CD4 count measured within three months
4
5 136 after these dates was chosen. Similar criteria were applied when establishing pVL at ART
6
7 137 initiation. To accommodate differential quantification limits across pVL monitoring assays (33),
8
9 138 values <50 copies/mL received the value 49 copies/mL and values >100,000 copies/mL received
10
11 139 the value 100,010 copies/mL.
12
13
14
15 140

141

141 **Statistical approach**

142 We explored the annual trends in time Dx-Tx and time Tx-Vx during 2005-2016. We also
143 examined the distribution of the two outcomes pre- and post-STOP, across gender, age, HA of
144 residence, CD4 count, ethnicity, and HIV acquisition risk groups to account for population
145 subgroup differences. Lastly, we estimated the relative effects of STOP on time Dx-Tx and time
146 Tx-Vx, adjusted for confounders.

147 Categorical variables were compared using the Fisher's exact test or Chi-squared test, and
148 continuous variables were compared using the Kruskal Wallis test (34). We modelled the
149 overdispersed time Dx-Tx and time Tx-Vx (i.e., as the number of months, respectively) using a
150 negative binomial regression model (35). Starting with a full model, confounding variables were
151 gradually omitted until the change in the coefficient for the main explanatory variable was $\geq 5\%$
152 (36). All p-values are two-sided, and the significance level was set at 0.05. Analyses were
153 performed in SAS version 9.4 (SAS, Cary North CA, USA) and R© version 3.6.0 (R Core Team,
154 Vienna, Austria).

155

156 **Ethics**

1
2
3 157 Linkage and usage of administrative databases were approved and performed by data stewards in
4
5 158 each collaborating agency and facilitated by the BC Ministry of Health. The University of British
6
7 159 Columbia Ethics Review Committee at the St. Paul’s Hospital site provided ethics approval for
8
9 160 this study (H18-02208). This study was conducted using strictly anonymized laboratory and
10
11 161 administrative databases, and thus informed consent was not required. This study complies with
12
13
14 162 the BC’s Freedom of Information and Protection of Privacy Act.

163 **Results**

164 **Study population**

165 Of the 3301 eligible PLWH diagnosed in BC during 2005-2016, 82% were male, 58% 30-49 years
166 old, 55% White, 51% Vancouver Coastal HA residents, 38% diagnosed with <350 CD4 cells/ μ L,
167 41% gbMSM (Table 1). Those diagnosed pre- and post-STOP (N=1601 [49%] vs. 1700 [51%])
168 were significantly different in demographic and clinical characteristics except for ethnicity. Of the
169 2979 PLWH (90%) who achieved suppression, those who initiated ART pre- and post-STOP
170 (N=998 [34%] vs. 1981 [66%]) were significantly different except in gender, ethnicity and HA of
171 residence.

173 **Time Dx-Tx**

174 The median time Dx-Tx substantially declined from 23 months ([25th, 75th percentile [Q1, Q3]: 4,
175 47) in 2005 to one month (Q1, Q3: 1, 2) in 2016 (Figure 1). The decline in time Dx-Tx pre- and
176 post-STOP was statistically significant across all population subgroups (Figure 2). Additionally,
177 post-STOP, the previously observed gaps in time Dx-Tx across age, CD4 count and HIV
178 acquisition risk groups have narrowed. For instance, pre-STOP, the median time Dx-Tx among
179 those <30 years old was 20 months longer than those ≥ 50 years old. Post-STOP, PLWH across
180 age groups initiated ART within a median of two months. Adjusted for confounder CD4 count at
181 diagnosis, time Dx-Tx was on average 65% shorter (adjusted mean ratio: 0.35 [95% confidence
182 interval: 0.32-0.38]) post-STOP.

184 **Time Tx-Vx**

1
2
3 185 Annual median time Tx-Vx declined from four months (Q1, Q3: 2, 6) in 2005 to one month (Q1,
4
5 186 Q3: 1, 3) in 2016, with PLWH initiating ART during 2007-2013 achieving suppression within a
6
7 187 steady median of three months (Figure 1). The decline in time Tx-Vx pre- and post-STOP was
8
9 188 statistically significant, except among females, Northern HA residents and those initiating ART
10
11 189 with 200-349 CD4 cells/ μ L (Figure 2). Post-STOP, Northern HA residents and PWID experienced
12
13 190 the longest median time Tx-Vx (4 months [Q1, Q3: 2, 9], respectively). On average, adjusted for
14
15 191 confounders HA of residence, CD4 count at ART initiation, HIV acquisition risk and type of first
16
17 192 ART, STOP was associated with 22% shorter time Tx-Vx (adjusted mean ratio: 0.78 [95%
18
19 193 confidence interval: 0.72-0.85]).

194 **Interpretation**

195 Within our universal healthcare setting, a TasP-based intervention was strongly associated with
196 earlier ART initiation and shorter time to virologic suppression, even when changes in ART
197 eligibility and first-line ART preferences were adjusted for. Observational studies from the
198 Netherlands, South Korea, Thailand and New York City also reported a significant decrease in
199 time Dx-Tx during 2012-2015 (37–40), when international guidelines began to recommend CD4-
200 count-independent rapid ART initiation (41–45). By 2015-2016, however, 75% of PLWH in BC
201 initiated ART within two months of their diagnosis, compared to 6 months in the aforementioned
202 jurisdictions (37–40).

203 While the independent impact of STOP's in accelerating time Dx-Tx in BC was evident,
204 the full public benefit of early ART to reduce transmission risk requires a decline in another more
205 complex time component, namely time from infection to diagnosis. Delayed HIV diagnosis has
206 previously been observed in one in seven BC's PLWH, particularly those who were older,
207 heterosexual, PWID and residing in Northern HA (46). This reality argues for targeted
208 interventions to improve HIV screening among the identified populations.

209 During our study period, other North American cohort studies also reported shorter time
210 Tx-Vx (47,48). Others reported faster suppression from the time of diagnosis (49–55), which can
211 be driven by shorter time Dx-Tx and/or time Tx-Vx. In 2016, BC's combined median time from
212 diagnosis to suppression was up to two months faster than the observations in several United States
213 jurisdictions (53,54). While our annual trends signalled that INSTI-based regimens likely
214 contributed to the faster decline in time Tx-Vx, our multivariable model corroborated the
215 independent impact of STOP.

1
2
3 216 In the present U=U era, a shortened time to achieve suppression is a critical measure of
4
5 217 HIV care success (56,57). This contention urges population-wide improvements in key risk factors
6
7
8 218 of virologic suppression, such as removing barriers to ART adherence, reducing substance use and
9
10 219 managing mental health disorders (58–60). While our study demonstrates BC’s remarkable
11
12 220 progress on rapid viral suppression by 2016, further studies should investigate how the coronavirus
13
14 221 disease pandemic may affect this progress. Interrupted healthcare access, medication disruption,
15
16
17 222 and psychological stress from self-isolation and income loss are among additional challenges faced
18
19 223 by PLWH during this pandemic, threatening progress on the control of HIV/AIDS (61–64).
20
21
22 224

23 24 225 **Limitations**

25
26 226 First, administrative health data are susceptible to coding errors. We thus used validated case-
27
28 227 finding algorithms specifically developed to ascertain HIV diagnosis dates in administrative
29
30 228 datasets. Second, our lack of granular ethnicity data limited our ability to fully assess ethnic
31
32 229 disparities in our outcomes. However, a recent study found no difference in HIV treatment
33
34 230 outcomes between indigenous and non-indigenous PWID in BC (65). Lastly, those recently
35
36 231 diagnosed may achieve virologic suppression after the administrative censoring date of March 31,
37
38 232 2017, and were thus excluded from the time Tx-Vx analysis. Given the high suppression rates, the
39
40 233 impact of this administrative censoring on our findings should be minimal.
41
42
43
44 234

45 46 47 235 **Conclusion**

48
49 236 Our large population-based study offers empirical evidence of the impact of a TasP-based
50
51 237 intervention in accelerating the progress of BC towards the UNAIDS’ 90-90-90 target. These
52
53 238 findings support the continued expansion of sustainable and equitable TasP-based policy and

13
14
15 **247 Competing interests**
16

17 248 JSGM has received institutional grants from Gilead Sciences and Merck. All other authors declare
18
19 249 no competing interests.
20

21 250

22
23
24 **251 Funding**
25

26 252 This work was supported by the following sources of funding: JSGM's Treatment as Prevention
27
28 253 (TasP) research, paid to his institution, has received support from the Public Health Agency of
29
30 254 Canada, and the British Columbia Ministry of Health. VDL is funded by grants from the Canadian
31
32
33 255 Institutes of Health Research (PJT-148595 and PJT-156147), and the Canadian Foundation for
34
35 256 AIDS Research (CANFAR Innovation Grant – 30-101). NGAN is supported by Canadian
36
37 257 Institutes of Health Research Canada Graduate Student – Master's Award and the University of
38
39 258 British Columbia's Four-Year Doctoral Fellowship. The sponsors had no role in the design, data
40
41 259 collection, data analysis, data interpretation, or writing of the report.
42
43

44 260

45
46
47 **261 Disclaimer**
48

49 262 The sponsors had no role in the design, data collection, data analysis, data interpretation, or writing
50
51 263 of the report. The corresponding author had full access to all data in the study and had final
52
53 264 responsibility to submit for publication. All inferences, opinions, and conclusions drawn in this

3 265 manuscript are those of the authors, and do not reflect the opinions or policies of the Data
4
5 266 Steward(s).

6
7
8 267

9
10 268 **Meeting**

11
12 269 Preliminary results were presented by NGAN at the 23rd International Workshop on HIV and
13
14 270 Hepatitis Observational Databases in Athens, Greece on March 28-30, 2019.

15
16
17 271

18
19 272 **Data statement**

20
21 273 The British Columbia Centre for Excellence in HIV/AIDS (BC-CfE) is prohibited from making
22
23 274 individual-level data available publicly due to provisions in our service contracts, institutional
24
25 275 policy, and ethical requirements. In order to facilitate research, we make such data available via
26
27 276 data access requests. Some BC-CfE data is not available externally due to prohibitions in service
28
29 277 contracts with our funders or data providers. Institutional policies stipulate that all external data
30
31 278 requests require collaboration with a BC-CfE researcher. For more information or to make a
32
33 279 request, please contact Mark Helberg, Senior Director, Internal and External Relations, and
34
35 280 Strategic Development: mhelberg@bccfe.ca. The underlying analytical codes are available from
36
37 281 the authors on request.

Note: Q1-Q3: 25th-75th percentiles; Time Dx-Tx: time from HIV diagnosis to ART initiation; Time Tx-Vx: time from ART initiation to viral suppression; gbMSM: gay, bisexual and other men who have sex with men; PWID: people with history of injection drug use; †: Variables were measured at the time of HIV diagnosis (for overall and time Dx-Tx analysis) or at ART initiation (for time Tx-Vx analysis); ‡: All participants in time Tx-Vx analysis were virologically suppressed; §: Variables were only measured at the time of ART initiation. For time Dx-Tx analysis, CD4 count was the only selected as confounder; for time Tx-Vx analysis, selected confounders included health authority, CD4 count, HIV acquisition risk and ART type.

Figure 1. The distribution of time from HIV diagnosis to ART initiation and from HIV ART initiation to viral suppression (measured in months) among people living with HIV in British Columbia from 2005-2016.

Note: Dx: HIV diagnosis; Tx: ART initiation; Vx: viral suppression. PLWH: people living with HIV

Figure 2. The distribution of time from HIV diagnosis to ART initiation and from ART initiation to viral suppression (measured in months) before and after STOP HIV/AIDS roll-out, stratified by selected demographic and clinical characteristics.

Note: Dx: HIV diagnosis; Tx: ART initiation; Vx: Viral suppression; North: Northern Health Authority; Coastal: Vancouver Coastal; Island: Vancouver Island. *Age, CD4 level and health authority of residence were measured at HIV diagnosis for time Dx-Tx and at ART initiation for the Tx-Vx, respectively. #Analyses for the unknown group is not shown. Time is in months, presented as median (25th percentile, 75th percentile). N/S: The difference in time before and after STOP HIV/AIDS was NOT statistically significant (p-value>0.05).
